Review: Major Components of a Computer

- Important metrics for an I/O system
 - Performance
 - Expandability
 - Dependability
 - Cost, size, weight

Input and Output Devices

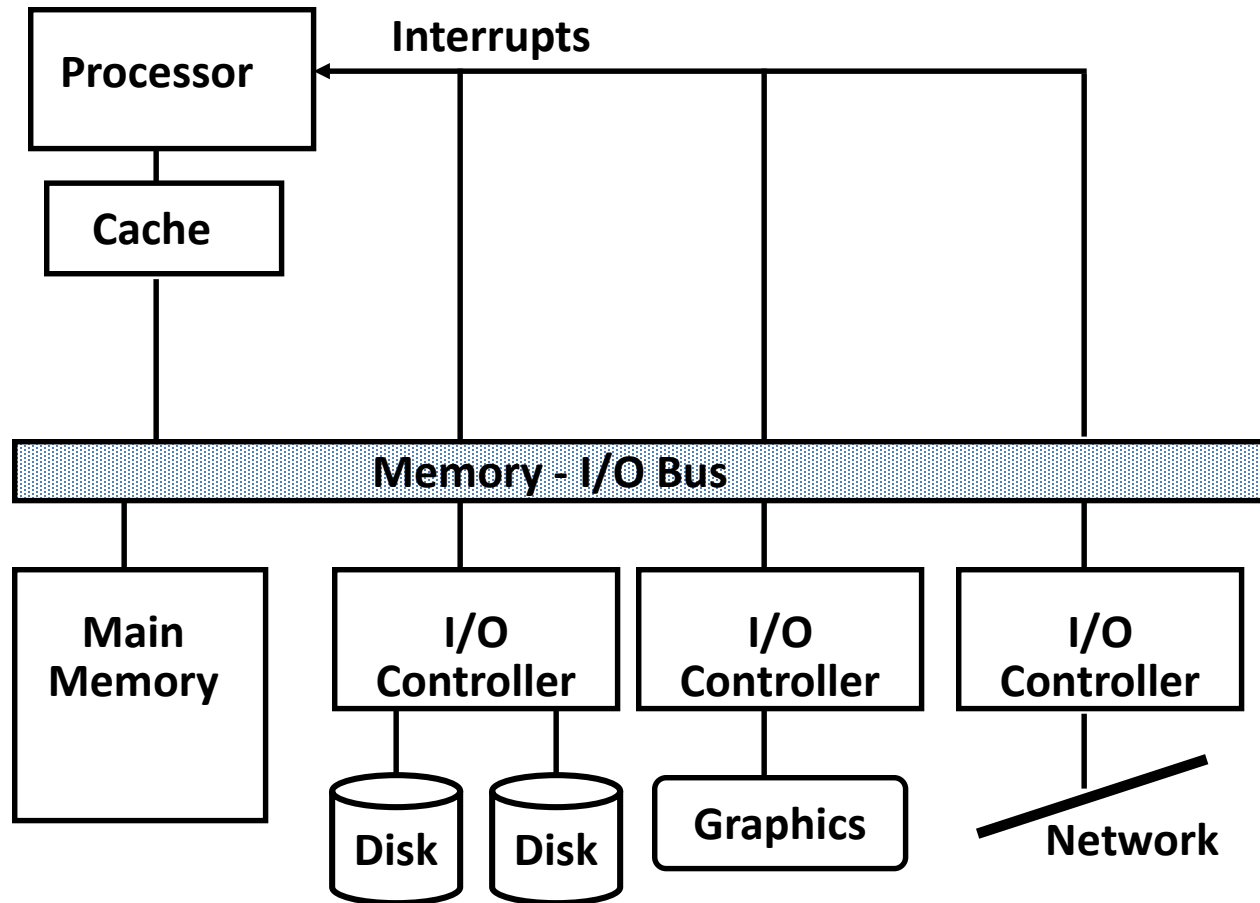

Device	Behavior	Partner	Data rate (Mb/s)
Keyboard	input	human	0.0001
Mouse	input	human	0.0038
Laser printer	output	human	3.2000
Graphics display	output	human	800.0000-8000.0000
Network/LAN	input or output	machine	100.0000-1000.0000
Magnetic disk	storage	machine	240.0000-2560.0000

8 orders of magnitude
range

I/O Performance Measures

- **I/O bandwidth** (throughput) – amount of information that can be input (output) and communicated across an interconnect (e.g., a bus) to the processor/memory (I/O device) per unit time
 1. How much data can we move through the system in a certain time?
 2. How many I/O operations can we do per unit time?
- **I/O response time** (latency) – the total elapsed time to accomplish an input or output operation
 - An especially important performance metric in real-time systems
- Many applications require both high throughput and short response times

A Typical I/O System

I/O System Performance

- Designing an I/O system to meet a set of bandwidth and/or latency constraints means
 1. Finding the weakest link in the I/O system – the component that constrains the design
 - The processor and memory system ?
 - The underlying interconnection (e.g., bus) ?
 - The I/O controllers ?
 - The I/O devices themselves ?
 2. (Re)configuring the weakest link to meet the bandwidth and/or latency requirements
 3. Determining requirements for the rest of the components and (re)configuring them to support this latency and/or bandwidth

I/O System Performance Example

- A disk workload consisting of 64KB reads and writes where the user program executes 200,000 instructions per disk I/O operation and
 - a processor that sustains 3 billion instr/s and averages 100,000 OS instructions to handle a disk I/O operation

The maximum disk I/O rate (# I/O's/s) of the processor is

$$\frac{\text{Instr execution rate}}{\text{Instr per I/O}} = \frac{3 \times 10^9}{(200 + 100) \times 10^3} = 10,000 \text{ I/O's/s}$$

- a memory-I/O bus that sustains a transfer rate of 1000 MB/s

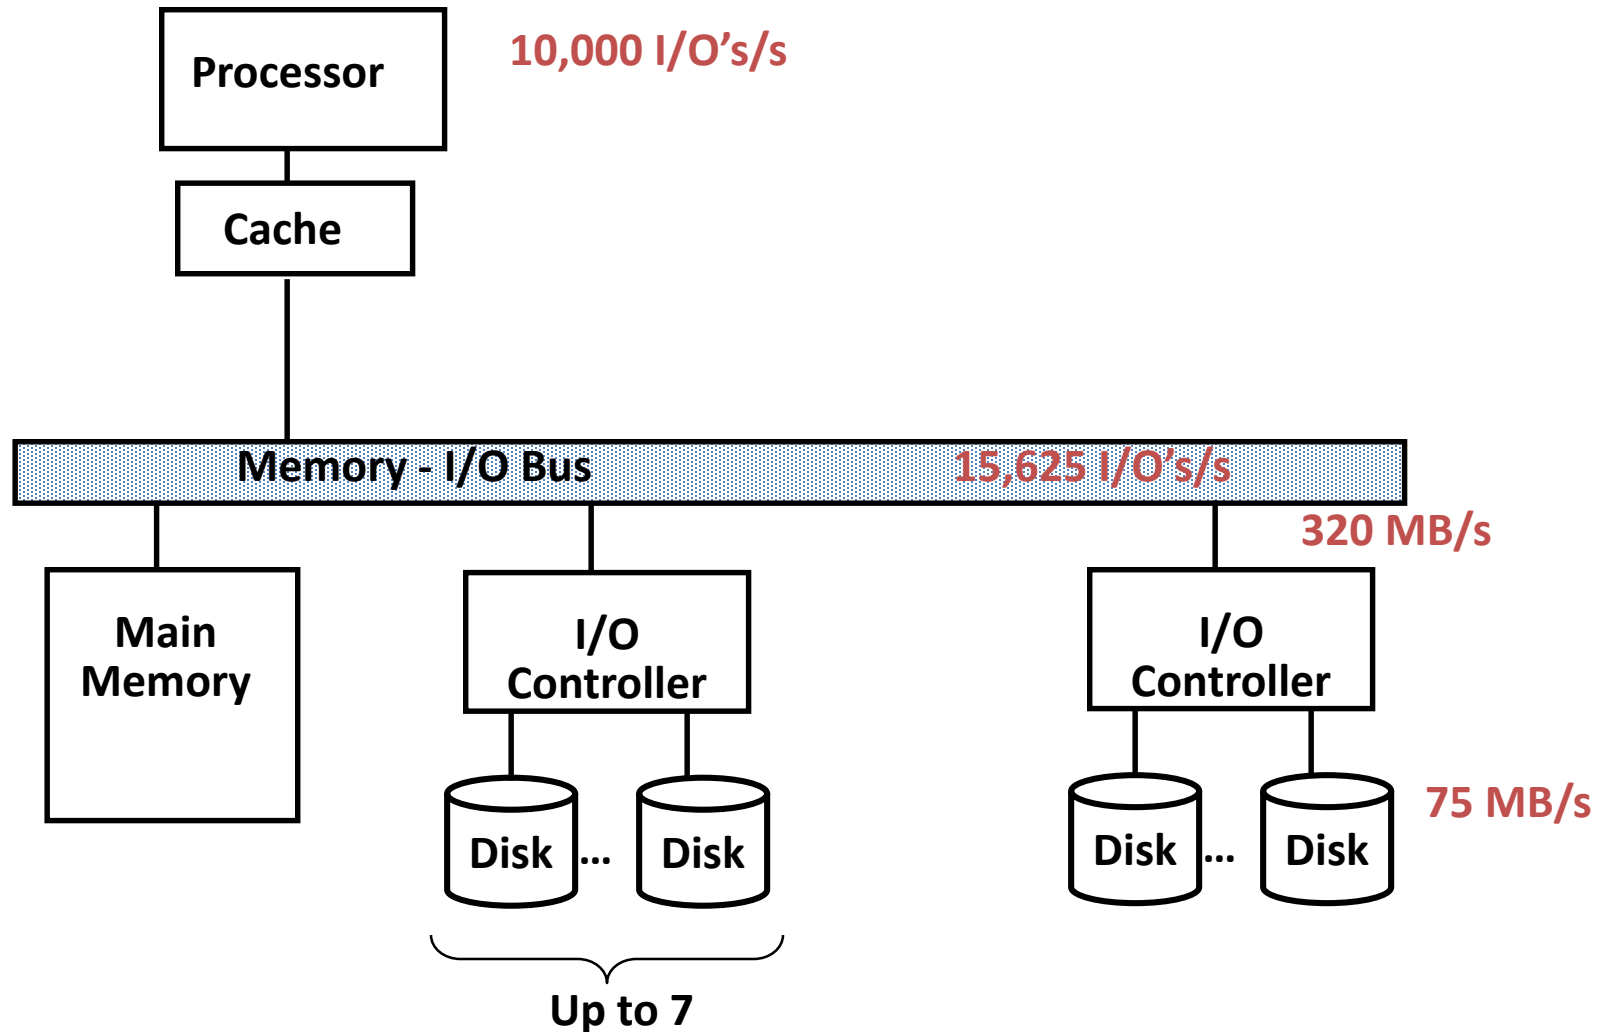

Each disk I/O reads/writes 64 KB so the maximum I/O rate of the bus is

$$\frac{\text{Bus bandwidth}}{\text{Bytes per I/O}} = \frac{1000 \times 10^6}{64 \times 10^3} = 15,625 \text{ I/O's/s}$$

- SCSI disk I/O controllers with a DMA transfer rate of 320 MB/s that can accommodate up to 7 disks per controller
- disk drives with a read/write bandwidth of 75 MB/s and an average seek plus rotational latency of 6 ms

what is the maximum sustainable I/O rate and what is the number of disks and SCSI controllers required to achieve that rate?

Disk I/O System Example

I/O System Performance Example, Con't

So the processor is the bottleneck, not the bus

- disk drives with a read/write bandwidth of 75 MB/s and an average seek plus rotational latency of 6 ms

Disk I/O read/write time = seek + rotational time + transfer time =
 $6\text{ms} + 64\text{KB}/(75\text{MB/s}) = 6.9\text{ms}$

Thus each disk can complete $1000\text{ms}/6.9\text{ms}$ or 146 I/O's per second. To saturate the processor requires 10,000 I/O's per second or
 $10,000/146 = 69$ disks

To calculate the number of SCSI disk controllers, we need to know the average transfer rate per disk to ensure we can put the maximum of 7 disks per SCSI controller and that a disk controller won't saturate the memory-I/O bus during a DMA transfer

Disk transfer rate = (transfer size)/(transfer time) = $64\text{KB}/6.9\text{ms} = 9.56 \text{ MB/s}$

Thus 7 disks won't saturate either the SCSI controller (with a maximum transfer rate of 320 MB/s) or the memory-I/O bus (1000 MB/s). This means we will need $69/7$ or 10 SCSI controllers.

I/O System Interconnect Issues

- A **bus** is a shared communication link (a single set of wires used to connect multiple subsystems) that needs to support a range of devices with widely varying latencies and data transfer rates
 - Advantages
 - Versatile – new devices can be added easily and can be moved between computer systems that use the same bus standard
 - Low cost – a single set of wires is shared in multiple ways
 - Disadvantages
 - Creates a communication bottleneck – bus **bandwidth** limits the maximum I/O **throughput**
- The maximum bus speed is largely limited by
 - The **length** of the bus
 - The **number** of devices on the bus

Bus Characteristics

- **Control lines**
 - Signal requests and acknowledgments
 - Indicate what type of information is on the data lines
- **Data lines**
 - Data, addresses, and complex commands
- Bus transaction consists of
 - Master issuing the command (and address) – request
 - Slave receiving (or sending) the data – action
 - Defined by what the transaction does to memory
 - Input – inputs data from the I/O device to the memory
 - Output – outputs data from the memory to the I/O device

Types of Buses

- Processor-memory bus (proprietary)
 - Short and high speed
 - Matched to the memory system to maximize the memory-processor bandwidth
 - Optimized for cache block transfers
- I/O bus (industry standard, e.g., SCSI, USB, Firewire)
 - Usually is lengthy and slower
 - Needs to accommodate a wide range of I/O devices
 - Connects to the processor-memory bus or backplane bus
- Backplane bus (industry standard, e.g., ATA, PCIe)
 - The backplane is an interconnection structure within the chassis
 - Used as an intermediary bus connecting I/O busses to the processor-memory bus

Bus Bandwidth Determinates

- The bandwidth of a bus is determined by
 - Whether its is synchronous or asynchronous and the timing characteristics of the protocol used
 - The data bus width
 - Whether the bus supports block transfers or only word at a time transfers

	Firewire	USB 2.0
Type	I/O	I/O
Data lines	4	2
Clocking	Asynchronous	Synchronous
Max # devices	63	127
Max length	4.5 meters	5 meters
Peak bandwidth	50 MB/s (400 Mbps) 100 MB/s (800 Mbps)	0.2 MB/s (low) 1.5 MB/s (full) 60 MB/s (high)

I/O Devices and Processor Communication

- How the processor directs the I/O devices
 - Special I/O instructions
 - Must specify both the device and the command
 - Memory-mapped I/O
 - Portions of the high-order memory address space are assigned to each I/O device
 - Read and writes to those memory addresses are interpreted as commands to the I/O devices
 - Load/stores to the I/O address space can only be done by the OS
- How the I/O device communicates with the processor
 - Polling – the processor periodically checks the status of an I/O device to determine its need for service
 - Processor is totally in control – but does **all** the work
 - Can waste a lot of processor time due to speed differences
 - Interrupt-driven I/O – the I/O device issues an interrupt to the processor to indicate that it needs attention

Interrupt-Driven I/O

- An I/O interrupt is **asynchronous** wrt instruction execution
 - Is not associated with any instruction so doesn't prevent any instruction from completing
 - You can pick your own convenient point to handle the interrupt
- With I/O interrupts
 - Need a way to identify the device generating the interrupt
 - Can have different urgencies (so may need to be prioritized)
- Advantages of using interrupts
 - Relieves the processor from having to continuously poll for an I/O event; user program progress is only suspended during the actual transfer of I/O data to/from user memory space
- Disadvantage – special hardware is needed to
 - Cause an interrupt (I/O device) and detect an interrupt and save the necessary information to resume normal processing after servicing the interrupt (processor)

Direct Memory Access (DMA)

- For high-bandwidth devices (like disks) interrupt-driven I/O would consume a *lot* of processor cycles
- DMA – the I/O controller has the ability to transfer data **directly** to/from the memory without involving the processor
 1. The processor initiates the DMA transfer by supplying the I/O device address, the operation to be performed, the memory address destination/source, the number of bytes to transfer
 2. The I/O DMA controller manages the entire transfer (possibly thousand of bytes in length), arbitrating for the bus
 3. When the DMA transfer is complete, the I/O controller interrupts the processor to let it know that the transfer is complete
- There may be multiple DMA devices in one system
 - Processor and I/O controllers contend for bus cycles and for memory

The DMA Stale Data Problem

- In systems with caches, there can be two copies of a data item, one in the cache and one in the main memory
 - For a DMA read (from disk to memory) – the processor will be using **stale** data if that location is also in the cache
 - For a DMA write (from memory to disk) and a write-back cache – the I/O device will receive **stale** data if the data is in the cache and has not yet been written back to the memory
- The coherency problem is solved by
 1. Routing all I/O activity through the cache – expensive and a large negative performance impact
 2. Having the OS selectively invalidate the cache for an I/O read or force write-backs for an I/O write (flushing)
 3. Providing hardware to selectively invalidate or flush the cache – need a hardware **snooper**

I/O and the Operating System

- The operating system acts as the interface between the I/O hardware and the program requesting I/O
 - To protect the **shared I/O resources**, the user program is not allowed to communicate directly with the I/O device
- Thus OS must be able to give commands to I/O devices, handle interrupts generated by I/O devices, provide equitable access to the shared I/O resources, and schedule I/O requests to enhance system throughput
 - I/O interrupts result in a transfer of processor control to the supervisor (OS) process
